Abstract - TITLE: - STUDY OF ANTEPARTUM HAEMORRHAGE & ITS MATERNAL & PERINATAL OUTCOME

AUTHOR: Dr. Archana Maurya, Dr. Sonal Arya. Dept of Obstetrics & Gynecology, Gajra Raja Medical College Gwalior

AIMS & OBJECTIVE: (I) To study factors association with Antepartum hemorrhage, (II) To study maternal morbidity and mortality due to A.P.H, (III) To study perinatal outcome in A.P.H

MATERIAL & METHOD: - In this study 100 cases of A.P.H admitted in Kamla Raja Hospital were studied and inclusion criteria of patients were Gestational age more than 28 wks with bleeding per Vaginum. All the cases were grouped as placenta previa, Accidental hemorrhage, local causes and unknown. The diagnosis was made on the basis of history, Clinical examination and few cases aided by ultrasonography.

RESULT: - Out of 100 cases of A.P.H, Placenta previa contributed to 71%, Abrupton placenta 27% and undetermined cause 2%. Maternal mortality out of 71 cases of placenta previa was 3 and 1 Abrupton placenta. Perinatal mortality was 12.69 in placenta previa and 18.52% in Abrupton placenta.

CONCLUSION: - A Ph is a major causes of maternal and perinatal morbidity and mortality which could he prevented by early registration, regular antenatal care, early detection of High risk cases, early referral to higher centre.

Index Terms- Antepartum haemorrhage, abruption placentae, placenta praevia, post partum haemorrhage.

I. INTRODUCTION

Obstetric haemorrhage is one of the three leading causes of maternal deaths and is also a major cause of perinatal morbidity and mortality.

II. MATERIAL AND METHODS

The material for this study comprises of 100 cases of antepartum haemorrhage admitted in Kamia Raja Hospital, Gwalior.

Inclusion Criteria:
1. Patients with bleeding per vagina after 28 weeks of gestation.

III. FIGURES
Out of 100 cases of APH there were 71 cases of placenta praevia giving incidence of 2.11%, 27 cases of abruptio placentae giving incidence of 0.80% and 2 cases of undetermined cause, hence placenta praevia contributed to 71% of the total cases of APH, abruptio placentae 27% and undermined causes 2%.
The table shows that incidence of placenta praevia is higher in age group 26-30 yrs i.e. 38.03% and in abruptio placentae incidence was higher in age group 21-25 yrs.

Incidence of APH due to placenta praevia was higher in 2nd and 3rd gravida patients 20 (28.17%) and 24(33.80%) cases respectively and incidence of aburptio placenta is higher in primi and 2nd gravida 14(51.85%) and 6 (22.22%) cases respectively.
Majority of cases i.e. 65% of APH belonged from rural area 35% from urban area 35%.

Majority of cases i.e. 62% of APH were unbooked emergency cases and the of booked cases was 38%.
The patients were graded according to kuppuswami’s classification the maximum cases were in class 5 and 4 were 56% (56 cases) and 36% (36 cases) whereas, in category 2 and 3 were 3% (3 cases) and 5% (5 cases) respectively.

In cases of placenta praevia maximum number 37 cases i.e. 52.11% were below 37 weeks.

Hence chances of preterm delivery were much more in placenta praevia, however majority of cases, 17 cases of abruptio placenta were found to be 2 cases of undermined cause among which 1 was preterm and 1 was term.
Hypertension was commonly associated with abruptio placentae.

The perinatal mortality was 12.68% (9 cases) in placenta praevia and 18.52% (5 cases) in abruptio placentae. Thus prevalence LBW babies and preterm babies with low apgar score is high in cases of APH leading of high parinatal mortality.
Perinatal mortality in case of APH is 15%.

Out of 71 cases of placenta praevia 3 (4.23%) patients died of severe haemorrhage and hypovolumic shock. There was 1 death (3.70%) amongst 27 patients of abruptio placentae. The cause of death was uncontrolled PPH leading to coagulation disorder.

IV. DISCUSSION

In present study there were 100 cases of APH. Out of 3369 deliveries giving incidence of 2.96%. This is similar to Feroza (1983) and Bhatt (1985)\(^7\). G. Roberts (1994)\(^8\). maximum cases of placenta praevia was in age 26-0 yrs. (3662%) which is similar to Penna and J.H. Pearee (1988)\(^16\), Nasreen (2003)\(^13\) studies.

Incidence of APH to be 82.1% in multigravida and 16.9% in primi. Hibbard reported 76% incidence in multipara. O'Donel
Browne, Menon (1990)\textsuperscript{15}, BCP Chan (1999)\textsuperscript{3} high incidence in multipara.

71 cases of placenta praevia 3 had curettage following spontaneous abortion. Correlated with the study of Barrett (1981)\textsuperscript{2}. 9 cases of placenta praevia had 1 previous section and 5 had previous 2 section giving an incidence of 6.39% and 3.55% respectively which is similar to Clark et al\textsuperscript{5}.

The incidence of placenta praevia type 1 is 9.5% type 2, 40.8%, type 3, 28.17% and type 4, 22.54 which is similar to P.N. Sura (1986)\textsuperscript{17}, Nasreen (2003)\textsuperscript{13} and Bahar and Abusham (2009)\textsuperscript{1} studies.

Malpresentation was seen in 25.36% cases which is similar to Macefee and Errol R. Norwitz (2010)\textsuperscript{12} studies. In our study 94.37% cases of placenta praevia were delivered by C. section and 2.82% delivered spontaneously, similar to study done in SSG Hospital Baroda 1989\textsuperscript{19} and study by Nusrat Nisar 2009\textsuperscript{14}.

In present study the incidence of PPH is 21.49% which is correlated with the study conducted by G. Roberts 1995\textsuperscript{9}, Nasreen 2003\textsuperscript{13}. Maternal mortality due to placenta previa is 4.23% and due to abruptio is 3.7%. Similar to study done by David K. Skinner 1991\textsuperscript{3}, HA Mansouri 2001\textsuperscript{10} SAguma Wiger 2002-04,\textsuperscript{18}

The perinatal mortality in cases of placenta praevia is 12.6 and 18.5 is abruptio placentae, which is similar to study conducted in Women Hospital Madras 1990\textsuperscript{20}. David K. Skinner (1997)\textsuperscript{6}.

V. RESULTS

Out of 100 cases of APH placenta praevia contributed to 71%, abruptio placenta 27% and undetermined caused to 2% of total cases of APH. Majority of cases i.e. 62% of APH were emergency cases and incidence of booked cases was 38%. Maternal mortality in APH showed out of 71 cases of placenta praevia 3 died of severe haemorrhage and 1 death in abruptio placentae. Perinatal mortality was 12.69 in placenta praevia and 18.52% in abruptio placentae. Prevalence of LBW babies and preterm babies is high.

VI. CONCLUSION

Antepartum haemorrhage is a major cause of maternal and perinatal morbidity and mortality which could be prevented by early registration, regular antenatal care, early detection of high risk cases, and early referral to higher centre. Good facilities for caesarean section, availability of blood banks. Use of contraceptives can improve maternal and perinatal outcome of APH.

ACKNOWLEDGMENTS

The author wish to thanks Dean Prof. Dr. S. Sapre, Gajra Raja Medical College, Gwalior Superintendent, Prof. Dr. S.N. Iyengar, J.A. Group of Hospital, Gwalior, Prof. Dr. V. Agrawal HOD, Department of Obstetrics and Gynaecology for permitting us to carry out the study.
