<http://dx.doi.org/10.29322/IJSRP.11.04.2021.p11231>

**Abstract:-Purpose:** It is well recognized that addressing patient safety related incidents have a positive impact on patient healthcare outcomes. However, health care professional's attitudes towards patient participation in patient safety were minimally assessed in Sri Lanka

**Methodology** This is a hospital-based descriptive, cross-sectional study were carried out in tertiary care Women's hospitals in the Colombo district. The sample size is 422. Stratified random sampling methods were used to get the required sample size. The data was collected using a self-administered questionnaire.

**Findings** Overall, there was a positive attitude for the patient involvement in patient safety in both women's hospitals among all three-health care professional categories.

**Originality/value** Comparison study of Perspectives of HCPs on patient involvement in patient safety survey, which was done in SL for the first time in a government woman's hospitals in Sri Lanka.

**Key words** - Patient involvement, HCP attitude, Patient safety

## 1 INTRODUCTION

Patient safety can, be defined as: 'The avoidance, prevention and reduction of adverse events or injuries stemming from healthcare delivery process' [1]. In a modern medicine, it is well recognized that patient safety is a key component of a patient care. Patient participation in their own healthcare depends on extend of health care professionals and patients' interpersonal relationship, provision of health-related information and involvement of clinical communication.[2]. It is well established that patient participation has a positive impact on favorable patient outcomes.

Health Care professionals (HCP) generally have a positive attitude towards patient involvement in patient safety. However, there are significant differences among different health care professional categories about patient safety. Therefore, we decided to include three different health care professional categories in our study include Doctors, Nursing Officers and Midwives. Our study conducted two leading women's hospital in Sri Lanka. De Soysa Hospital for Women (DSHW) is the oldest women's hospital in Sri Lanka has a bed strength of 343 with a annually around 7500 births. Castle Street Hospital for Women (CSHW). is the premier women's hospital in Sri Lanka has a bed strength of 442 with a annually performing around 12000 deliveries.

It is well recognized that addressing patient safety related incidents have a positive impact on patient healthcare outcomes. However, patient safety related factors and health care professional's participation in patient safety were minimally assessed in Sri Lanka. Two women's hospitals were used in the study have a certain extend of patient safety culture with a significant difference in two women's hospitals. Therefore, study was designed to analyze the health care professionals' perspectives on patient

involvement in patient safety in two women's hospitals and to identify key differences among the which will obviously provide a initiate patient safety program and to strengthen existing systems of patient safety culture.

### General Objective

Comparison study of attitudes toward supporting patient involvement in patient safety as a Health Care Professionals (HCP) among two women's hospitals

### Specific Objectives

1. To Compare the HCP attitudes towards the factual questions among two women's hospitals
2. To Compare the HCP attitudes towards the Challenging questions among two women's hospitals
3. To Compare the HCP attitudes towards the Notifying questions among two women's hospitals 4.To Compare the HCP attitudes towards the Information provision questions among two women's hospitals
5. To Compare the HCP attitudes towards the Reporting incidents questions among two women's Hospitals.

### Methodology

This is a hospital-based descriptive, cross-sectional study were carried out in tertiary care Women's hospitals in the Colombo district namely De Soysa Hospital for Women (DSHW) and Castle Street Hospital for Women (CSHW). The study was carried out Ten months period of time and data collected two months period of time in each hospital. Study population included those who were attached to five obstetrics and gynaecological units at CSHW and four obstetrics and gynaecological units at DSHW were included for the study. Selected Health Care Professionals (HCP) in this study include Consultants, Postgraduate trainees, Senior Medical Officers, Relief House Officers, Intern Medical Officers, Nursing Sisters, Grade Nursing Officers and Midwives.

Sample size were 422 calculated according to Lwanga and Lemeshow, 1991 formula. Stratified Random sampling method were carried out to get the required sampling size. The data collected instruments were self-administered questionnaire. Focus group discussion was held at Quality unit at CSHW. Aim of the focus group discussion was to adapt of the questionnaire to suit local conditions. some variables were omitted from the questionnaire used in that study due to inapplicability in the Sri Lankan context. A few variables were added in relation to the working condition and to suit the Sri Lankan context.

Questionnaire -01 was developed to assess the basic socio –demographic characteristics of the participants.

Questionnaire- 02 was developed comprising 22 items to assess selected HCP attitudes to support patient involvement in different safety related behaviors. Three main categories of “interactional behaviors” were examined that involve engaging in dialogue with selected HCP: asking factual questions (05 items), challenging questions (5 items) and notifying selected HCP problems or errors in their care (04 items). Two categories were used to assess attitude to support “non-interactional behaviors” this include information provision questions (05 items) and incident reporting questions (03 items). The responses to these questions were assessed in the Likert Scale. The principal investigator was checked the data collected before it was fed into the computer for analysis. The data was checked for missing and unused values. The data entry was carried out in SPSS 20 statistical package. Ethical approval of the study was obtained from ethical review committee Post Graduate Institute of Medicine, University of Colombo. Approval were also obtained from the Directors of CSHW and DSHW concerned were also informed of the study and necessary approval was obtained. Explanation were made to them on the nature of the study, expectation from participants,

and how confidentiality would be ensured. The voluntary nature of the participants was explained.

**Results**

Table 03 displays comparison of doctors in two women’s hospitals regarding attitudes toward Supporting patient involvement in patient safety as a selected HCP. Overall doctors had positive attitude towards patient involvement as HCP in both hospitals. Most of the items doctors in both hospitals no significant difference noted except two. Item of “Information provision” and “Incident reporting” showed significantly higher score from CSHW compare to DSHW (P <0.05).

Table 05 shows comparison of midwives in two women's hospitals regarding attitudes toward Supporting patient involvement in patient safety as a selected HCP. Result showed midwives at CSHW were scoring significantly higher in two components, namely "Incident reporting" questions and "Information provision" questions ( $P < 0.01$ ). For the "Factual questions", midwives got the significantly higher results ( $P < 0.01$ ).

## Discussion

Comparison of two women's hospitals showed similarities and dissimilarities between two health care institutions. Comparison of doctors of two hospitals as a HCPs' showed that doctors at CSHW had more positive attitude than DSHW doctors in three components and out of which, two components were statistically significant also (Table 03). (Information provision questions and incident reporting questions). Doctors at DSHW scored more in challenging questions however, that was not statistically significant. Studies on doctors' attitudes on medical errors indicate that majority assumed that patients are somewhat responsible for mistakes and errors during their treatment procedures [3]. Another studies showed that providing adequate information to the patient is the better way of minimizing errors and adverse events related to health care[4]. Study done in Nepal found that healthcare professionals have positive attitudes towards adverse drug reactions reporting. Increasing awareness among healthcare professionals, training and collaboration would likely to improve reporting [5].

Comparison of nurses among two women's hospitals as a HCPs showed one component (challenging questions) by CSHW nurses and two components (notifying questions and incident reporting questions) by DSHW nurses were in more favour of patient safety and those were statistically significant also (Table 04). In a Swedish study involving nurse's on patient safety, nurses intimated that provision of rational patient's data is a facilitator for patient safety [6]. Another, study on patient perspective of involvement in their care has emphasized that value of patients realizing their important data , engaging in treatment procedures and to compose informed decisions.[7],[8],[9]

Comparison of midwives' perspectives on patient involvement in patient safety as a HCP result showed that CSHW getting higher marks for four components and out of two were statistically significant (Table 05). Only one component was statistically significant in DSHW.

## Conclusion:

Overall, there was a positive attitude for the patient involvement in patient safety in both women's hospitals among all three-health care professional categories. However, CSHW health care professionals showed strong support towards patient safety compared to DSHW.

### Limitations of the study

our research was confined to two women's hospitals in Colombo and involving obstetric and gynaecological specialties. Therefore, our research findings need to be generalized to apply for general population.

## RECOMMENDATIONS

Negative attitudes on incident reporting need to be emphasized. It's useful to highlight HCPs' about the nature of incident reporting that is as a fact finding process rather than fault finding procedure. Establishing a patient safety culture will play key role in changing their behaviour. Updating or developing guidelines on incident reporting and distributing among HCPs'can **encourage**

## their behaviour

## ACKNOWLEDGMENT

It is with great pleasure for me to express my sincere gratitude to my supervisor Dr.S.Sridharan, Deputy Director General (Planning) for believing me throughout the completion of the research. I must also sincerely thank all the consultants, doctors, nurses and midwives of Castle Street Hospital for Women and De Soysa Hospital for Women for the support rendered me during the period of my study. Last but not least, I would like to thank my parents and friends who helped me in numerous ways, always stood behind me and for their kind co-operation and tolerance throughout my research period.
