Abstract- In most of the cases two coronary arteries supply oxygenated blood to the heart, the right coronary artery (RCA) and the left coronary artery (LCA). One of the important branches of RCA is the conus artery (CA) which supplies the infundibulum of the right ventricle or pulmonary conus.

In the present study Computed Tomographic (CT) coronary angiograms of 50 subjects of north Indian population were analyzed prospectively to see the pattern of origin and number of conus artery. One of the most important variant of origin of conus artery is the third coronary artery (TCA). The incidence of TCA was also assessed.

All the subjects were undergone multidetector CT coronary angiography in the department of Radiodiagnosis KGMU, U.P, Lucknow. One conus artery was seen in 47 (94%) subjects. Out of these 47 subjects, conus artery arose from the RCA in 38 (76%) cases and from the anterior aortic sinus (AAS) of ascending aorta in 9 (18%) cases. In these 9 cases, conus artery acts as third coronary artery. In some cases RCA and conus artery have separate orifice in the AAS and some cases have common orifice for RCA and conus artery. Two conus arteries were observed in 1 (2%) case. In this case one artery arose from AAS (third coronary artery) and second from RCA. In 2 (4%) cases conus artery was not visualized. In this way third coronary artery was seen in 10 (20%) cases.

The third coronary artery represents a significant path of collateral coronary circulation as it often anastomoses with left anterior descending (LAD) branch of LCA.

Index Terms- Computed Tomography (CT), Conus Artery (CA), Coronary Angiogram, Third Coronary Artery (TCA).

I. INTRODUCTION

An in-depth knowledge of the anatomy of coronary arteries is a pre-requisite for a detailed understanding of the coronary artery disease (CAD) and for planning of cardiovascular surgery. In most of the cases the heart is supplied by two coronary arteries right and left. Sometimes third coronary artery is present. Normally the conus artery is a branch of RCA. According to Schlesinger TCA is the conus artery arising directly from the anterior aortic sinus (AAS) [21]. This third coronary artery may be a boon for the person having it. This artery when present may help in the establishment of partial identity of an individual, if ante mortem records of coronary angiograms are available [4].

Occurrence and distribution of third coronary artery is important for accurate understanding of coronary angiograms, assessment of severity and effect of coronary insufficiency and appropriate preparation for timely revascularization of ischemic myocardium. Usually the conus artery is the first right ventricular branch of the RCA which originates from the first part of RCA (extending from origin to the junction of right and inferior borders of the heart). The conus artery supplies the pulmonary conus or outflow portion of the right ventricle. Several authors had suggested that conus artery is a collateral arterial channel between the right and left coronary arteries.

This study was done with an aim to assess the variations in the origin and number of conus artery and the frequency of third coronary artery in North Indian population. The findings of this study would be of great significance in the interpretation of coronary angiograms and for surgical revascularization of ischemic myocardium.

This was a prospective study in which 64-slice computed tomographic (CT) coronary angiograms of 50 subjects were visualized. Third coronary artery was seen in 10 (20%) subjects. The third coronary artery plays a significant role in collateral circulation of the heart because it anastomoses with a branch of left anterior descending (LAD) artery. The results of this study provide an extensive knowledge of the origin of conus artery which is required for the diagnostic and therapeutic interventional procedures done on coronary arteries.

II. MATERIAL AND METHODS
CT coronary angiograms of 50 subjects of both sex and different age groups [32 males (14-75 years), 18 females (12-70 years); mean age 51.36 ± 14.07 years, age range 12-75 years] were analyzed.

**Scan protocol and image reconstruction**

Coronary Angiography (CA) was performed in all subjects using a 64-Slice Multidetector Computed Tomographic (MDCT) scanner (BRILLIANS 164CT, Version 2.45.22042, Philips) installed in the department of Radiodiagnosis, King George Medical University (KGMU), Lucknow, Uttar Pradesh (U.P.), India. Retrospective Electrocardiographically (ECG) gated imaging was performed. The scan field extended from the carina to the diaphragm. The imaging parameters were: slices/detector collimation of 64x0.625 mm, effective temporal resolution (with 180° algorithm) of 165 ms, tube voltage of 120 kV, tube current of 800 mA, gantry rotation time was 400 ms, pitch of 0.2, slice thickness of 0.90 mm and 0.45mm reconstruction interval. Field of view (FOV) was 220mm. Isotropic voxel resolution 0.4×0.4×0.4 mm. A single inspiratory breath-hold of approximately 10-12 seconds (scanning time) completed the examination.

**Pre-procedure precautions**

- The subjects were enquired, to rule out the presence of any drug allergy to avoid the occurrence of any untoward anaphylactic reaction during the procedure.
- The subjects were advised to avoid the intake of fatty food two days prior to the procedure.
- They were advised to drink only water just prior to the procedure.
- Blood urea and creatinine levels were evaluated.

**Procedure**

The subjects were laid supine. Their heart rate was stabilized with an oral dose of 50-100 mg Metoprolol one hour before the scan. If heart rate was not stabilized with an oral dose, then intravenous (IV) Metoprolol was given. Electrocardiogram (ECG) and pulse rate were monitored half an hour prior to the procedure. The subjects were counseled to reduce their anxiety.

The subjects were connected to a cardiac monitor. For venous access, an upper extremity vein (antecubital vein) and a 20-gauge intravenous canula was used. 80-85 ml of non-ionic contrast Iohexol (Omnipaque, GE, GE Healthcare Ireland, Cork) containing iodine concentration of 350 mgI/ml, injected with a flow rate of 5.5ml/sec, followed by a 20 ml saline flush at a rate of 4ml/sec with a pressure injector (PSI-325). The scan timing was determined with automated bolus tracking technique by placing the region of interest over mid ascending aorta and setting the trigger threshold to 180 Hounsfield (Hu). The subjects were asked to lie still on the “scanning bed” for a period of 10 minutes. The instruction was given to the subjects to maintain an inspiratory breath hold during which CT data and ECG tracings were taken. Computed Tomographic Coronary Angiography (CTCA) was performed 5 seconds after aortic peak density. Scanning coverage was from the level of carina to the diaphragm. Raw spiral CT data of coronary arteries were reconstructed in various phases of cardiac cycle on a workstation (Brilliance 64 version 4.5) to obtain images with the highest quality (without motion artefact). This work station enabled generation of the images of coronary arteries in the standard and in various other anatomical planes. Reconstruction performed at 75% of R-R interval was found to be optimal for image analysis in most of the subjects. In some, if heart rate could not be stabilized properly, then reconstructions were performed at 45% of R-R interval. The reconstructed images were interpreted with the help of a cardiac radiologist. Subjects with previous bypass surgery and also those with suboptimal study due to breath hold artefacts were excluded.

All images were reviewed first in axial projection and then with post processing tools such as Multiplanar Reconstruction (MPR), Curved Planar Reformation (CPR), thin-slab Maximum Intensity Projection (MIP), and Volume-Rendering Technique (VRT) with transparent background display. MIPs were obtained using various thicknesses (5–30 mm). Volume-rendered images were also obtained using various orientations.

The statistical analysis was performed by using software SPSS (Statistical Package for Social Sciences) version 15.0. The values were represented in Number (%) and Mean ± Standard Deviation (SD).

**III. RESULTS**

In the present study, the number and the origin of conus artery were observed.

**Variable Number and Origin of Conus Artery**

One conus artery was seen in 47 (94%) subjects [29 (90.63%) males and 18 (100%) females]. (Table 1 & Bar Diagram 1). Out of these 47 subjects, conus artery was seen arising from the RCA in 38 (76%) cases (Fig.1a,b,c &d) and from the anterior aortic sinus of ascending aorta in 9 (18%) cases (Fig.2 & Fig.3). In these 9 cases, conus artery acts as third coronary artery. In some cases RCA and
CONUS ARTERY have separate orifice in the AAS(Fig.2) and some cases have common orifice for RCA and conus artery (Fig.3). Among the 38 cases of origin from RCA, 23 (71.88%) were males and 15 (83.33%) were females. Among the 9 cases of origin from ascending aorta 6 (18.75%) were males and 3 (16.67%) were females(Table 2 & Bar Diagram 2).

Two conus arteries were observed in 1 (2%) case [1 (3.13%) male] (Table 1 & Bar Diagram 1). In this case one artery arose from AAS (third coronary artery) and second from RCA (Fig.4a). In 2 (4%) cases [2 (6.25%) males], conus artery was not visualized. (Table 1 & Bar Diagram 1)(Fig.4b).

IV. DISCUSSION

Usually the first branch of right coronary artery (RCA) is the pulmonary conus artery or conus artery (CA). If the conus artery arises directly from the aorta it is named as third coronary artery. Incidence of this type of origination is between 7% to 50%(Table - 3)[21].

Present study has revealed the incidence of third coronary artery (TCA) to be 20%. Other studies have reported various incidences as shown in Table- 3. The findings of present study are similar to Udaya Sankari et al, 2011[21] and nearer to Pinar Kosar et al., 2009[13].

The findings of different studies mentioned in Table3 show ethnic variability and appear to support a catheter angiographic study by Naveen Garg et al., 2000 in which they proposed that there are geographical differences in coronary artery variations, which may have a genetic basis [11].

The conus artery supplies the pulmonary infundibulum and the supraventricular crest. It usually anastomoses with a branch from the left coronary artery. This anastomosis lies on the distal part of the bulbous cordis (truncus arteriosus) and is known as the Vieussens’ arterial ring [25].

Collateral circulation is a key factor in the pathophysiology of Coronary Artery Disease (CAD). Symptoms and prognosis among patients with advanced CAD depend largely on the degree of collateral circulation [18]. The conus branch of the RCA has a special anatomical and functional significance in the development of collaterals between the right and left coronary arterial systems. The conus artery may also arise as a separate branch from the aorta, and may not even be visualized by selective angiography due to its small size in patients with mild disease, only manifesting itself in advanced CAD when it is recruited to provide collateral circulation to under-perfused myocardial territories [14].

Kurjia HZ, et al., 1986 found ectopic orifice of conus artery in AAS to be anomalous rather than ubiquitous [9]. Sahni and Jit in 1989 reported extra openings for conus artery in 34.8% of male hearts and 27.8% of female hearts [17]. In the present study, extra orifice for conus artery in AAS was seen in 21.88% of males and 16.67% of females (Table 2).

Since the conus artery does not arise from the RCA always, the study of its origin gains importance for angiographic dye injection. An aberrant conus artery arising separately from the aorta is particularly at risk for injury from ventriculostomy or other maneuvers performed during heart surgery [22]. According to the opinion of Edwards and Miyazaki the third coronary artery is more frequently found in adult hearts than in fetal hearts, concluding thereof that it develops only after birth [2,10].

In 1988 a stereoscopic study of Miyazaki M & Kato T, suggested that the third coronary artery develops and contributes to the collateral circulation after birth. They also found that pathologic hearts had a higher incidence than normal hearts but there is no relation to age and the orifice of TCA was wider in pathologic hearts than normal hearts [10].

The separate orifices for the TCA and the RCA had been explained by insufficient unification of these two vessels, during their growth towards the ascending aorta [16, 26]. The branches of TCA open up in some cardiac pathology to provide collateral perfusion and they have been shown to improve with age [20]. TCA may contribute to collateral circulation to the interventricular septum (IVS) during left anterior descending (LAD) occlusions hence protecting the septum. The clinical implication of this is that diagnostic tests carried out for the LAD occlusions may fail to detect any ischemic change in this region hence giving a false better report [26].

The TCA may extend epicardially to supply the apex of the heart. Therefore a caution should be taken during surgical procedures around the anterior wall of the RV and infundibulum since such a long TCA may present a surgical hazard [12]. Ivan Stankovic et al. (2004) suggested that the folding of the heart results in opening of the existing peritruncal capillaries at the cono-truncal circle either directly into the newly formed aorta resulting in multiple ostia or secondarily attached to the existing blood vessels surrounding the atroventricular circle resulting in the right conus artery arising from right coronary artery [6]. The knowledge of ontogeny of the right conus artery requires further detailed study in foetuses.
V. CONCLUSION

The present study adds to the growing body of data on intrapopulation frequencies of conus artery variants among North Indians and supports the contention that postpartum development may modify the pattern of coronary divergence from the aorta. As the number of Caucasian patients undergoing surgical treatment for ischemic or valvular heart disease increases, additional comparative data on racial, sexual, and ontogenetic variation of the origin and number of conus artery are required to improve the care of these patients.

ACKNOWLEDGMENT

I sincerely acknowledge my heartfelt gratitude to my respected teachers Dr. P.K. Sharma, Dr. Punita Manik, Dr. Pallavi Aga and Dr. Ragini Singh and other teaching staff of the department of Anatomy and department of Radiodiagnosis, KGMU, the management and Principal of Goldfield Institute of Medical Sciences and Research for their constant and kind support, valuable suggestions and encouragement to carry out this work.

I am grateful to the technical staff of the department of Radiodiagnosis, KGMU, Lucknow for their assistance in the procurement of digital copies of coronary angiograms analyzed in this study.
