Abstract- Background: 75% of calcaneal fractures are intra articular. Treating calcaneal fractures is a challenge for orthopaedic surgeon due to the complex fracture pathology. A wide range of treatment options varying from non operative to operative methods are available. The purpose of this study is to assess the functional outcome of conservatively treated and operatively managed intra articular calcaneal fractures. Methods: 24 intra articular fractures have been classified as per Computerized Tomography based Sanders system. 12 fractures were treated conservatively. 12 fractures were treated with open reduction and internal fixation with plating. Functional outcome was assessed using Modified Rowe score after following the cases over mean period of 18 months. Results: In conservatively managed 12 fractures, average functional outcome score was good in 7 Sanders Type-I fractures, average functional outcome score was satisfactory in 3 Sanders Type-II fractures and was poor in 2 Type-III Sanders fractures. In fractures fixed with open reduction and internal fixation with plating, average functional outcome score was excellent in 7 Sanders Type-II fractures and good in 5 Sanders Type-III fractures. Conclusion: Sanders Type-I fractures can be treated conservatively with good functional outcome. Managing Sanders Type II and III conservatively results in satisfactory to poor outcome. Hence for Sanders Type-II and Type-III, Open reduction and internal fixation with plating has to be considered for achieving excellent functional outcome.

Index Terms- Calcaneum, conservative, plating, screws, Sanders classification, Modified Rowe scale.

I. INTRODUCTION

Calcaneum fractures account for 2% of all fractures, 60% of tarsal bone fractures. 10% of fractures are bilateral and 75% are intra articular. 10% of fractures are associated with vertebrae fractures. Mechanism of injury in majority of patients is axial loading i.e. fall from height. Other mechanisms are brake pedal injuries and high velocity trauma. Current development in imaging technology has allowed better understanding of this complex fracture pathology. Sanders classification of intra articular Calcaneum fractures is widely used now a days because of its proven correlation with management and prognosis. Treating Calcaneum fractures is a challenge for orthopaedic surgeon. Treatment options ranges from non operative to operative methods. Some studies show advantage to internal fixation whereas some show no difference. Hence, a study has been carried out with the aim to assess the functional outcome of conservatively and operatively managed intra articular calcaneal fractures.

II. MATERIALS AND METHODS

There were 24 intra articular fractures in 22 patients in 1 year which were treated. Mean patient age was 35 years. 20 patients were male (90.9%) and 2 were females (9.1%). Right Calcaneum was involved in 12 cases (50%), 8 cases (33.33%) had left Calcaneum fracture, 2 cases (16.66%) had bilateral calcaneum fractures. Mechanism of injury was fall from height in all patients. 2 patients (9.09%) had associated vertebra fractures without neurological deficit. Patients were evaluated clinically and radiologically, lateral (Fig.1.), axial (Fig.2.) radiographs of Calcaneum were taken. Routine pre operative Computerized Tomography (Fig.3.) was taken. Sanders system (Table 1) was used for classifying intra articular fractures. 12 intra articular fractures (50%) which included Sanders type-I, poor local condition, medically unfit patients, peripheral vascular isease and patients who are unwilling for surgery have been treated conservatively with limb elevation and immobilization in plaster for 8 weeks. 12 intra articular fractures (50%) were fixed internally under fluoroscopic guidance on an average in 10 days of injury once wrinkle sign is positive. The aim of treatment was to achieve articular surface reconstruction, to restore height, width of axis of heel by performing primary osteosynthesis.
Extensile lateral approach (Fig.4.) was used in all cases which were internally fixed with plating (Fig.5.). Axial and Broden views were assessed under fluoroscopy intra operatively. Satisfactory reduction was achieved in all cases. For comparison of corrected Bohlers and Gissane angles, post operative radiographs were taken (Fig.8.).
Post operatively limb elevation was maintained for 72 hours. Compressive bandage was applied over sterile dressing. Complete suture removal was done at an average of 15 days. All operated patients were kept on absolute non weight bearing for 4 weeks followed by touchdown weight bearing with active and passive movements of ankle and sub talar joints. Full weight bearing was allowed from 12 weeks. Regular clinical follow up examination was performed monthly in all cases and functional outcome was assessed by using Modified Rowe scale (Table 3) after following the cases over a mean period of 18 months.
III. RESULTS

There were 24 intra-articular fractures in 22 patients in 1 year which were treated. 12 intra-articular fractures (50%) were treated conservatively. 12 intra-articular fractures (50%) were surgically managed by open reduction and internal fixation with locking plates. Mean patient age was 35 years. 20 patients were male (90.9%) and 2 were females (9.1%). Right Calcaneum was involved in 12 cases (50%), 8 cases (33.33%) had left Calcaneum fracture, 2 cases (16.66%) had bilateral Calcaneum fractures. As per Sanders classification Type-I fractures were 7 (29.16%), Type-II were 11 (45.83%), Type-III were 6 (25%). 7 Sanders type-I fractures (100%) were treated conservatively. Out of 11 Sanders Type-II fractures, 3 (27.27) were treated conservatively, 8 (72.72%) with open reduction and internal fixation. Out of 6 Sanders type-III fractures, 2 (33.33%) were treated conservatively and remaining 4 (66.66%) were operated with open reduction and internal fixation with plating. Pre operatively Bohler’s angle was decreased to average of 15 degrees. Post operatively Bohler’s angle was restored to average of 30 degrees. Post operative average Gissane angle was 110 degrees.

Patients Distribution as per functional outcome as per Modified Rowe score:

Table 1:
- Modified Rowe score: 
  - Excellent >85
  - Good 70-85
  - Satisfactory 55-70
  - Poor <55

In conservatively managed 12 fractures-average functional outcome score was good in 7 Sanders Type-I fractures, average functional outcome score was satisfactory in 3 Sanders Type-II fractures and was poor in 2 Type-III Sanders fractures. Average functional outcome score was excellent in 8 Sanders Type-II fractures and good in 4 Sanders Type-III fractures fixed with open reduction and internal fixation. In patients treated with open reduction and internal fixation with plating, wound dehiscence was seen in 1 patient (8.33%) which was healed with clean compressive dressings. No other complications were observed.

IV. DISCUSSION

Intra-articular fractures account for approximately 75% of calcaneal fractures, and are commonly associated with other axial load injuries giving rise to lumbar vertebral fractures. Mechanism of injury of the Calcaneum fracture causes a major soft tissue injury that includes heel pad, skin and other soft tissues.
Lateral, axial and Broden view radiographs are used to examine calcaneal fractures. CT diagnostic provided improved understanding of calcaneal fractures and led to a clinically relevant classification of these injuries. CT scans give additional information on (1) the size and number of fracture fragments, (2) the size and displacement of sustentacular tali relative to superior medial fragments, (3) the presence of a step or diastasis of the posterior facet, and (4) impingement of the fibular malleolus on the tuberosity of the Calcaneum. Such scans also provide information regarding fractures involving the sinus tarsi, calcaneocuboid joint, and anterior calcaneal process, all of which could be relevant while planning the lateral surgical approach. Thus a better surgical planning became possible. CT evaluation of calcaneal fractures has allowed classification systems to offer prognostic significance.

Sanders classification based on C.T was used in our study (Table 2). Table 2: Sanders Type3

I Non-displaced fracture irrespective of the number of fracture lines
II Two parts fragment or split fracture
III Three parts fracture or split depression
IV Four parts fracture or highly comminuted

Sanders classification: Table 2.

The treatment goals are: (1) restoration of congruency of the posterior facet of subtalar joint, (2) restoration of the calcaneal height and width, (3) decompression of the sub fibular space available for the peroneal tendons, (4) realignment of the tuberosity in a valgus position, and (5) reduction of the calcaneocuboid joint. Small subtalar incongruity of only 1 mm can lead to early arthrosis of the corresponding joints. Conservative treatment is sufficient in Sanders Type I fractures which results in good functional outcome. Operative methods of treatment have included attempts at closed reduction or percutaneous manipulation, percutaneous screw fixation, open reduction with internal fixation, bone grafting or both, and primary arthrodesis of the subtalar joint. To correct calcaneal anatomy, open reduction should be advised to patients. Open reduction and internal fixation is now more aggressively advocated for management of displaced Sanders type II or III calcaneal intra-articular fractures to achieve anatomical reduction, to decrease the complication of subtalar arthritis and joint incongruity. Because of the risk of early complications, the timing of surgery i.e. after local swelling subsides is of principal importance. We used the lateral extensile approach because it provides wide exposure of the subtalar joint and allows more accurate exposure of the facet fragments and calcaneocuboid joint, easier decompression of the lateral wall, and sufficient area laterally for plate fixation. Other options, though not used in our study is plating and bone grafting to prevent collapse and maintain the height of Calcaneum and to add mechanical support and to probably stimulate earlier fracture healing. As lateral wall is subcutaneous, any implants on the surfaces can lead to early post-operative complications like wound dehiscence, necrosis of wound edges, and early superficial infection. Use of percutaneously screw fixation with minimum soft tissue dissection can be opted which also results in less post operative swelling and considerably yields good functional outcome. The functional outcome in our study was assessed by using Modified Rowe scale (Table 3).

http://dx.doi.org/10.29322/IJSRP.9.10.2019.p9419
Our study showed that in conservatively managed fractures, average functional outcome score was good in Sanders Type-I fractures, satisfactory in Sanders Type- II fractures and was poor in Type-III Sanders fractures. Fractures fixed with open reduction and internal fixation with plating, average functional outcome score was excellent in Sanders Type-II fractures and good in Sanders Type-III fractures.

V. CONCLUSION
Sanders Type-I fractures can be treated conservatively with good functional outcome. Managing Sanders Type II and III conservatively results in satisfactory to poor outcome. Hence for Sanders Type-II and Type-III, Open reduction and internal fixation with plating has to be considered for achieving excellent functional outcome.
