Design of a Humanoid Robot using High Speed Internet for Communication

Shyam R. Nair, Prof. Manjula Pramod

Dept. of EIE, Hindustan University, Chennai, India

Abstract- This paper focuses on the design of a 30 DOF self securable humanoid robot using high speed internet for communication. The robot consists of hip, neck, shoulder, elbow, wrist and finger joints. The robot secures itself from hacking and power problems. The robot is controlled by a combination of a human master and a local master connected to a sensor fusion unit.

Index Terms- Humanoid, DOF, High speed internet, hacking, sensor fusion unit.

I. INTRODUCTION

Robot is a machine to execute different task repeatedly with high precision. Thereby many functions like collecting information and studies about the hazardous sites which is too risky to send human inside. Robots are used to reduce the human interference nearly 50 percent. Robots are used in different types like fire fighting robot, metal detecting robot, etc. Humanoids are robots which resembles human joints. Humanoids are nowadays used in industrial purpose, military, research etc.
This paper focuses on designing a 30 DOF humanoid robot. The software is schemed in such a way that the humanoid can secure itself from hacking and power problems. The robot is controlled by a human master and a local master controller which is connected to a sensor fusion network.

II. HARDWARE CONCEPT

A. Mechanical Part

The humanoid consists of a hip, neck, shoulder, elbow, wrist and finger joints. The humanoid has 30 degrees of freedom.

The humanoid has a platform on which it is mounted. The platform helps the humanoid to move around in a plane surface. The platform consists of four wheels each of which is connected to dc geared motors. The hip joint of the humanoid has one degree of freedom and allows the upper body of the humanoid to rotate in horizontal direction. The neck joint helps to rotate the head in horizontal direction. A web camera is mounted in the eyes of the humanoid.

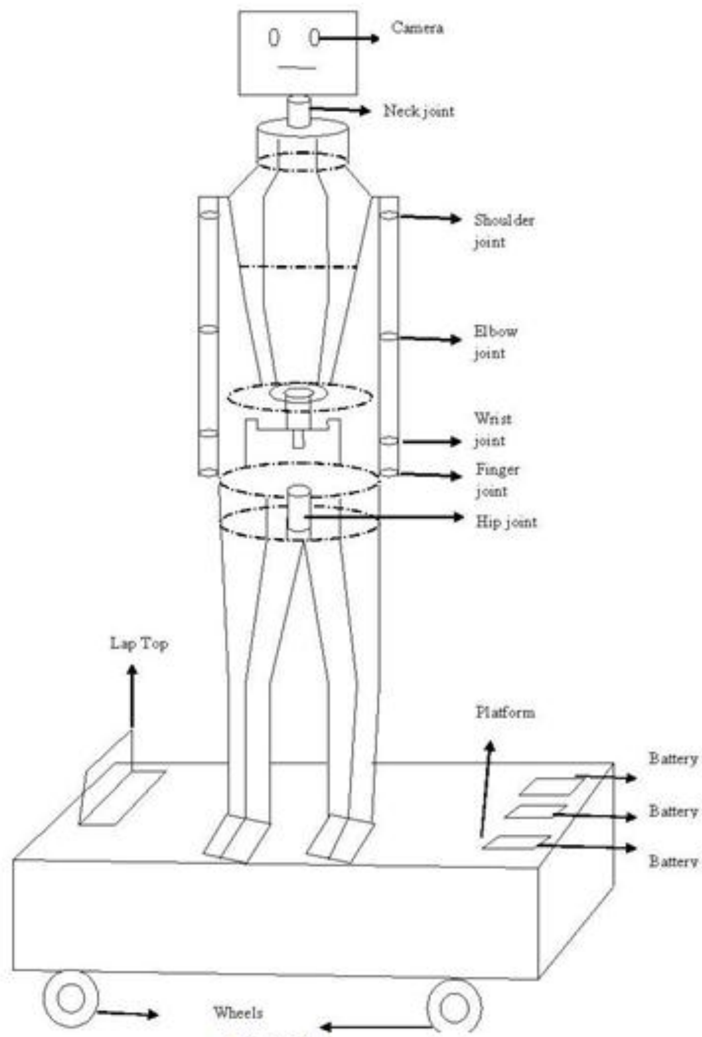

Figure 1
Schematic

The humanoid has shoulder, elbow, wrist and finger joints on both hands. The shoulder has 2 DOF, elbow has 3DOF, wrist has 4 DOF and the finger unit has 5 DOF. All these togather makes 30 DOF humanoid.

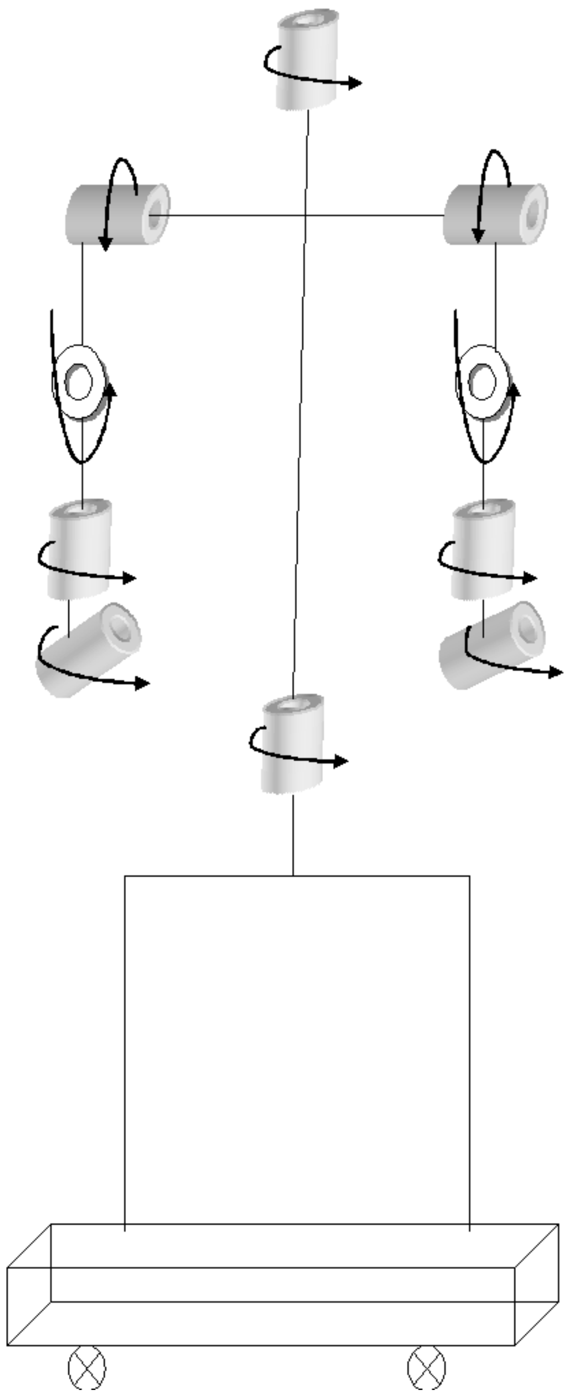

Figure 2: Schematic of motor arrangement

A. Mathematical Calculations

There are 14 motors with 10 rpm each including the four in the platform which are connected to the wheels.

Neck motor:
The motor is placed at neck which will make the head rotate in the horizontal plane.
Weight of the head including the web camera is 0.5 Kg.
The distance from the shaft of the motor is 25 cm.
Hence torque required to make proper movement is
0.5*6 = 3 Kgcm

Required power = 2*π*N*T/60
= 3.12 Watts
Where N is rpm of the motor and T is torque

Hip motor:
The motor is placed at hip which will make the upper body rotate in the horizontal plane.
Weight of the upper body is 5.5 Kg.
The distance from the shaft of the motor is 30 cm.
Hence torque required to make proper movement is
5.5*30 = 165 Kgcm
the required torque is 50% of the calculated torque due to the symmetry of the upper body.
Hence actual torque = 82.5 Kgcm.
Required power = 2*π*N*T/60
= 85.8 Watts

Shoulder motor:
The motor is placed at the shoulder which will make the hand rotate in the vertical plane.
Weight of the hand is 1.5 Kg.
The distance from the shaft of the motor is 70 cm.
Hence torque required to make proper movement is
1.5*70 = 105 Kgcm
the required torque is 50% of the calculated torque as one of the end is hinged which supports the rotation.
Hence actual torque = 52.5 Kgcm.
Required power = 2*π*N*T/60
= 54.95 Watts

Elbow motor:
The motor is placed at elbow which will make the arm rotate in the horizontal plane.
Weight of the arm is 0.6 Kg.
The distance from the shaft of the motor is 20 cm.
Hence torque required to make proper movement is
0.6*20 = 12 Kgcm
the required torque is 50% of the calculated torque as one of the end is hinged which supports the rotation.
Hence actual torque = 6 Kgcm.
Required power = 2*π*N*T/60
= 6.24 Watts

Wrist motor:
The motor is placed at the wrist which will make the palm yoke.
Weight of the palm is 0.3Kg.
The distance from the shaft of the motor is 20 cm.
Hence torque required to make proper movement is
0.3*20 = 6 Kgcm
Required power = 2*π*N*T/60
= 6.24 Watts

Finger motor:
The motor is placed at the finger which will make the finger grasp.

Weight of the finger unit is 0.05Kg.
The distance from the shaft of the motor is 10 cm.
Hence torque required to make proper movement is
0.05*10 = 0.5 Kgcm
Required power = 2*π*N*T/60
= 0.52 Watts.

Wheels motor:
The motors are coupled to the wheels of the platform for free movement in a plane surface.
The weight of the body is equally distributed to four wheels. Thus each wheel will bear a load of 10Kg.
Distance of the wheel from axis of the motor= 2cm.
Hence torque required for 1 wheel is 10*2 = 20Kgcm.
Required power = 2*π*N*T/60
= 20.8 Watts

III. ELECTRONICS

The platform is designed to fit a laptop, sensors, and four 12V 7aH lead acid batteries. The platform also contains the electronics hardware including a relay based circuit for driving the dc geared motors, a pic microcontroller circuits, and ultrasonic sensors.

The task to be executed is given as voice commands [14] by the human master at the client pc. A serial code is generated for each word and is transmitted to the laptop on the robot platform. For generating, transmitting and receiving the code software's known as Roboclient and Roboserver is used. Both these software's are developed in Microsoft Visual Studio. The client pc and the server laptop is connected to internet using high speed 3G network. The serial code is transmitted from the laptop to the microcontroller circuit by a RS-232 cable. When the microcontroller receives this signal, it checks for the environmental conditions using the ultrasonic sensors. The environmental condition, here, refers to any obstacle for the task execution. Now if there are no obstacles, then, the robot executes the task. But if there is any obstacle, it sends the human master a serial code indicating its problem and waits for further instruction from human master. The human master can view the area under survey with the help of the camera mounted on the robot platform. This is made possible by using the Gmail video chat or the Skype software.

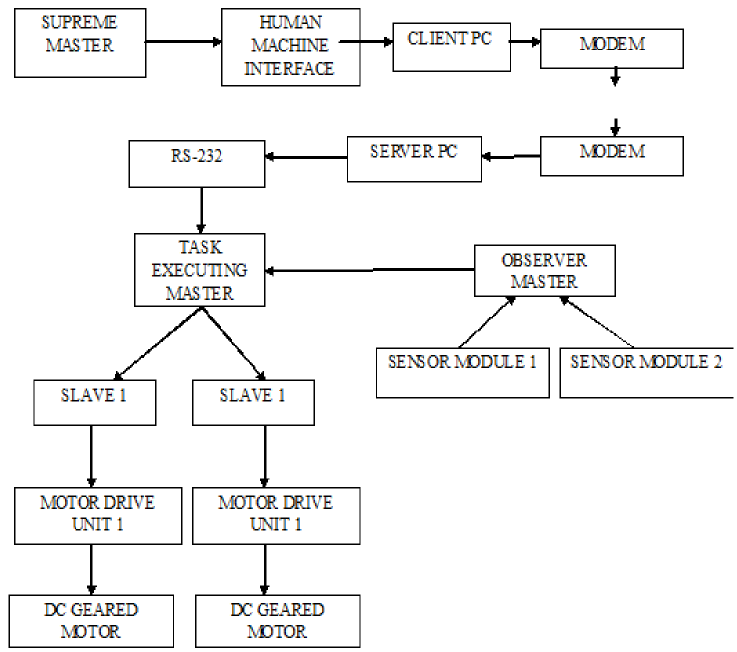
The robot platform also contains a battery monitoring circuit. If this circuit identifies a power crisis, then, the circuit switches to the next power source. The number of power sources can be fixed according to the need and availability. If the last battery is switched, then, the robot closes all its applications and comes back to the source point by using the data in the eeprom. The robot also returns to the source point if it identifies a security issue in the communication link.

Identification of a security issue in communication link

The client pc and the server laptop continuously exchange a serial code. If the pic microcontroller does not receive this code in a specified delay, it comes to a conclusion that the communication link is lost or hacked. In that case, the robot closes all its communication links and other activities and returns back to the source point. By using the data stored in eeprom.

Returning of robot to the source point using the data in eeprom

The robot stores all the movement codes in the internal eeprom of the pic microcontroller. The first location contains the movement code and the next location contains the time delay for the code. This continues for all the movement codes. When the robot faces a security or power problem, the robot executes the data in eeprom in last in first out method. The controller swaps the forward and backward instructions. That is if there is a forward movement in the eeprom location, the robot moves backward and vice versa. The rest of the instructions remain the same. This helps robot from protecting itself from exploitation from unauthorized access.



A. *Visual sensor*

This part is the place to install sensors which are used for searching vital sign of the victims like camera [11]. The camera can be made to continuously rotate as per the command from human master. The visuals obtained by the camera are transmitted through the Gmail video chat or the Skype software.

B. *Monitoring and navigation of robot*

The robot is monitored using the camera in the robot platform. The robot uses ultrasonic sensors for identifying any obstacle in the path of its motion. The sensors are connected to the controller circuit for making appropriate decision. When the robot navigates automatically, it uses the data in eeprom. For the patrol robot navigation several methods are used like sensing the paths, graphical user interface, map following algorithms and compass, other Kalman filtering methods[6][5][7][8][9]. All these approaches are somehow complex. This can be overcome by using the EEPROM of the microcontroller. PIC16F877A has

256 bytes of EEPROM inside it. So memory can use it to store data that need on a permanent basis and we can read it back from it. There are two functions to accomplish the task. Eeprom_Read and Eeprom_Write.

Eeprom_Read function returns an integer and takes a parameter of the address from which the data has to be fetched. Eeprom_Write takes two parameters the first one is the address and the second one is the data.

unsigned short Eeprom_Read(**unsigned int** address);

void Eeprom_Write(**unsigned int** address, **unsigned short** data);

Most of the robot will navigate with different algorithm.[10][11][12][13] The robot will navigate with respect to the commands from the user (initially from A to B) as shown in fig.7. All the running commands are stored in the memory and also a counter is set to determine how long the commands are executed. Now the current position of the robot is at B. Whenever it needs to return, the last stored command will execute first (LIFO). If the last executed command is forward, that swaps it into backward command.

Similarly,

Backward ≈ Forward

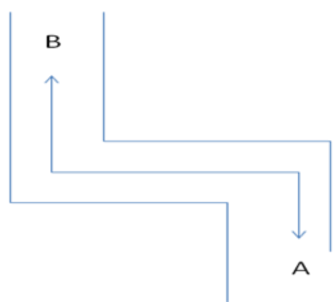


FIGURE 4: PATH SCHEMATIC

IV. SOFTWARE

Onboard software is mainly developed with micro C. This software interfaces between the operator station software and the robot by receiving operator's command to control all robot functions. Simulations have been executed both in Mat lab and PIC simulator. In Mat lab the approaches were implemented under ideal hypothesis, more realistic settings. The commands are send through serial communication with the help the software Roboclient developed in Microsoft Visual studio. The data is received using the software Roboserver developed in Microsoft Visual studio. Real time visuals can be captured and displayed on the window with the help of Gmail video chat or Skype software.

V. SAMPLE WORKING

The required action is commanded by the human master as a specific word which is picked by the microphone and converted to a code alphabet by the client PC using Roboclient software. This alphabet is transmitted to the server laptop at the robot platform through high speed internet. At the reception end the alphabet is transmitted to the master controller from the server laptop through RS-232 cable. Now the master controller controls the slaves according to the program for the particular alphabet.
For example, when a command 'move' is said by the human master, a code alphabet 'm' is transmitted and the microcontroller on receiving this 'm', executes the internal loop program and waits for the next instruction.

VI. CONCLUSION

The 30 DOF humanoid robots were designed successfully and were found to have advantages of unbounded control with the use of high speed internet. The humanoid also has the advantage of self securing ability.

ACKNOWLEDGMENT

The research in this paper was carried out at Hindustan Institute of Technology and science, Chennai. This work was supported by the e-MEN Robotic Research Centre Palakkad.
